TO MERGE OR TO LICENSE: IMPLICATIONS FOR COMPETITION POLICY

Ramón Faulí-Oller and Joel Sandonís

ABSTRACT

The optimal competition policy when licensing is an alternative to a merger to transfer a superior technology is derived in a di¤erentiated goods duopoly, for the cases of Cournot and Bertrand competition. We show that whenever both royalties and …xed fees are feasible, mergers should not be allowed, which …ts the prescription of the U.S. Horizontal Merger Guidelines. By contrast, when only one instrument is feasible, be it …xed fees or royalties, the possibility of licensing cannot be used as a de…nitive argument against mergers.

KEYWORDS: Merger; Patent Licensing; Competition Policy.

1. INTRODUCTION

Nowadays, companies all over the world seem to have an insatiable appetite for mergers, with the goal of capturing complementarities, scale economies, integrating technologies and production facilities and achieving cost e¢ciencies. This phenomenon demands a severe control by antitrust authorities to prevent anticompetitive behaviors. For example, until 1997, Section 5 of the 1992 U.S. Horizontal Merger Guidelines (HMG), prescribed to forbid mergers whenever the e¢ciency gains were less than their competitive risks or whenever "equivalent or comparable savings can reasonably be achieved by the parties through other means". In April 1997, however, section 5 on e¢ciencies was extended to explicitly include among those "other means" the possibility of licensing: "The Agency will consider only those e¢ciencies...unlikely to be accomplished in the absence of either the proposed merger or another means having comparable anticompetitive e¤ects. These are termed merger-speci...c e¢ciencies...The agency will not deem e¢ciencies to be merger speci...c if they could be preserved by practical alternatives that mitigate competitive concerns, such as...licensing."

It is well known the increasing importance played by licensing in the di¤usion of new technologies in the last few years. For example, Arora and Fosfuri (1998) document a widespread incidence of licensing in the chemical industry. Anand and Khanna (1997) report that licensing is also very common in biotechnology and ...nd that licensing has increased in frequency between 1990-1993 (the time period of their study). Finally, evidence of the importance of licensing in computers, automotive, biopharmaceuticals, engineering and electronics is also reported in di¤erent surveys.

The rationale behind the 1997 HMG prescription seems to rely on the idea that, while a merger facilitates the di¤usion of technology at the cost of reducing market competition, a licensing contract is an e¢cient instrument to transfer technology. However, as we show in the paper, the optimal contract to transfer a superior technology to a rival ...rm includes always a positive royalty (very often accompanied by a ...xed fee) that (i) increases the licensee's marginal cost above its true marginal cost, softening in that way market competition and (ii)

under Bertrand competition, it works as a collusive device that allows the ...rms to commit themselves to higher prices. Therefore, the welfare comparison between a merger and a licensing contract becomes ambiguous. The sign of the comparison depends on whether social welfare is a ected more negatively by the lower level of competition induced by a merger or by the distortion of the licensee's marginal cost induced by a licensing contract. The main goal of this paper is to determine which of the two e exects dominates.

We compare social welfare under both a merger and a licensing contract in a di¤erentiated goods duopoly for the cases of Cournot and Bertrand competition, in order to derive the optimal competition policy, and check whether that policy ...ts the prescription of the 1997 HMG. We show that, regardless of the type of competition, whenever both ...xed fees and royalties are feasible instruments to license the superior technology, a licensing contract is welfare superior to a merger, which ...ts the prescription of the 1997 HMG.

Nevertheless, when only one instrument, either ...xed fees or royalties, can be used by the patentee, the HMG is shown to be too restrictive because it could lead to forbid welfare improving mergers. In particular, when only a ...xed fee is included in the licensing contract,¹ the HMG is too restrictive because, regardless of the type of competition, for close enough substitute goods and large enough innovations, licensing by means of a ...xed fee becomes unpro...table for the patentee. In those cases, a merger becomes the only exective instrument to transfer the superior technology and, hence, it should be allowed whenever it is welfare improving. On the other hand, if we consider the case where only royalties are feasible,² the patentee sets a greater royalty, distorting even more the licensee's output and thus additionally reducing welfare. In those cases and regardless of the type of competition, for large enough innovations a merger becomes welfare superior to licensing and socially desirable and it should then be allowed.

After deriving the optimal merger policy, we extend the analysis to take into account

¹The optimal contract to license a cost reducing innovation to a rival ...rm includes always a royalty (Faulí-Oller and Sandonís (2000a)), provided that the licensee's output is veri...able. Otherwise, royalties are not feasible, which can explain in our context the use of ...xed fee contracts.

²That situation could arise due, for example, to the existence of a high degree of riskiness associated to the innovation, that precludes the use of ...xed fees.

that, under Bertrand competition, a licensing contract may reduce social welfare. As a consequence, interesting new cases appear where, under the optimal competition policy, not only mergers but also licensing should be forbidden.

Regarding the existing literature on mergers, Williamson (1968) already pointed out the trade o^a involved in a merger: on the one hand, it reduces competition but, on the other hand, it may generate e¢ciency gains. Several papers have derived alternative ways of evaluating this trade-o^a (Farrell and Shapiro (1990), Levin (1990), Mac A^aee and Williams (1992)). On the other hand, the issue of merger pro...tability has been addressed, among others, by Salant et al. (1983), Perry and Porter (1985), Deneckere and Davidson (1985) and Lommerud and Sorgard (1997).

With respect to the licensing literature, it has mainly focused on comparing the performance of ...xed fees and royalties as instruments to market cost-reducing innovations. Under perfect information, Kamien and Tauman (1984,1986), Katz and Shapiro (1986), Muto (1993) and Erutku and Richelle (2000) analyze the case of an external to the industry patentee. On the other hand, Katz and Shapiro (1985), Wang (1998) and Faulí-Oller and Sandonís (2000a) extend the analysis to the case of an internal patentee. Finally, including asymmetric information problems, Gallini and Wright (1990), Macho-Stadler and Pérez-Castrillo (1991), Macho-Stadler et al. (1996) and Hornsten (1998) show that both fees and royalties should be included in the optimal licensing contract. Nevertheless and to the best of our knowledge, there is no paper in literature that relates these two ...elds by considering both a merger and a licensing contract as two alternative instruments to transfer technology.

The remainder of the paper is organized as follows: Section 2 presents the model. Section 3 derives the optimal merger policy for both Cournot and Bertrand competition. In section 4, the analysis is extended to take into account the possibility that a licensing contract reduces social welfare. Finally, a section with the main conclusions closes the paper. All formal proofs have been relegated to the Appendix.

2. THE MODEL

We consider two ...rms, denoted by i = 1,2, each producing a dimerentiated good (goods 1 and 2 respectively). They face inverse demand functions given by:

$$p_i = 1 i x_i j ^{\circ} x_j; i; j = 1; 2; i \in j;$$

where ° 2 [0; 1] represents the degree of product di¤erentiation. Following Singh and Vives (1984), these demands come from the maximization problem of a representative consumer with utility separable in money (m) given by:

$$u(x_1; x_2) = x_1 + x_2 i \frac{x_1^2}{2} i \frac{x_2^2}{2} i ^{\circ} x_1 x_2 + m$$

The direct demand functions are given by³:

$$x_i = \frac{1}{1+\circ}_i \frac{p_i}{1_i^{\circ 2}} + \frac{p_j}{1_i^{\circ 2}}; i; j = 1; 2; i \in j:$$

Firm 2 has constant unit production costs of c. Firm 1 is assumed to have a patented process innovation that allows to produce good 1 at a lower marginal cost, that we set, without loss of generality, to be zero. Two di¤erent mechanisms to transfer the patented technology to ...rm 2 are considered: a licensing contract and a merger. Both mechanisms are assumed to reduce the marginal cost of producing good 2 to zero⁴.

Depending on the size of the innovation we will distinguish between drastic and nondrastic innovations. We will call an innovation drastic when it allows the patentee to monopolize its market. In particular, this is the case if $c > c^{M}$; where $c^{M} = \frac{2_{i}}{2}$:

³Direct demands are not de...ned for $^{\circ} = 1$: Therefore, under Bertrand competition, we will restrict the analysis to the case in which the goods are not homogeneous, that is, $^{\circ} 2$ [0; 1).

⁴Notice that this assumption implies that both instruments allow the perfect and complete transmission of the innovation. In other words, we consider both instruments equivalent from a technological point of view, ignoring problems of asymmetric information between licensor and licensee, as well as the possibility that a merger can create synergies that could give a merger a technological advantage over licensing. Considering licensing and mergers technologically equivalent, while making the analysis tractable, will not signi...cantly a¤ect the qualitative results we obtain. Its main consequence will be that, when deriving the optimal competition policy in this setting, we will never be too permissive with respect to mergers.

Incorporating the fact that ...rm 1's marginal cost is assumed to be zero, let us de...ne the social welfare function as:

$$W(x_1; x_2) = u(x_1; x_2) i c_2 x_2;$$

where $c_2 = 0$ if ...rm 1's technology is transferred and $c_2 = c$ otherwise.

The timing of the game is the following:

In the ...rst stage, the antitrust authority decides whether or not to allow a merger between ...rms 1 and 2. In the second stage, the ...rms have the possibility to merge (if allowed in the ...rst stage) or to sign a licensing contract. Given this decision, market competition takes place in the third stage, with the cost functions inherited from the second stage. We will solve by backward induction, obtaining the subgame perfect Nash equilibrium of the proposed game.

We will consider three di¤erent licensing scenarios: (1) two-part tari¤ (f; r) contracts, (2) royalty (r) contracts and (3) ...xed fee (f) contracts, where f represents a ‡at lumpsum license fee and r represents a per unit of output fee (royalty). Scenario 2 could arise for example when riskiness associated to the innovation precludes the use of fees. Scenario 3, when royalties are not feasible due, for example, to lack of veri...ability of the licensee's output. Otherwise, scenario 1 arises. The licensing game is modelled as follows: ...rst, the patentee makes a take-it-or-leave-it o¤er to ...rm 2; second, this ...rm accepts or rejects the contract. We do not allow for negative fees because, otherwise, as argued by Katz and Shapiro (1985), contracts would include the possibility for the patent holder to "bribe(s) ...rm 2 to exit the industry...and would likely be held to be illegal by antitrust authorities."⁵ It should be noted that the licensee's marginal cost whenever a royalty is included in the licensing contract (scenarios 1 and 2) is given by r and thus, the patentee plays the role of a leader, as he determines the reaction function of the licensee by deciding the royalty to be included in the contract. On the other hand, under fee licensing (scenario 3) or under a merger, ...rm 2's marginal cost becomes zero.

⁵Notice that we do allow for contracts including negative royalties. Nevertheless, for the case of substitute goods, it is never optimal for the patentee to charge a negative royalty. This would be the case, however, for complementary goods, that are not considered in this work.

In the next section, we shall proceed to solve the game in order to derive the optimal merger policy under the three possible licensing scenarios. For the two ...rst scenarios we will present together the analysis and the results for both Cournot and Bertrand competition, so that we can easily compare both regimes.

3. THE OPTIMAL MERGER POLICY

At the third stage of the game, if the ...rms have merged in the previous stage, the merged entity will produce the monopoly outputs for the two goods. Otherwise, the ...rms will compete either in quantities (Cournot) or in prices (Bertrand), with the marginal costs inherited from the second stage. If no licensing contract has been signed, the statu quo will prevail. On the other hand, under a licensing contract and Cournot competition they solve respectively:

$$Max_{x_1}fp_1(x_1; x_2) x_1 + rx_2g;$$

$$Max_{x_2}fp_2(x_1; x_2) x_2 i rx_2g;$$

where $p_i(x_1; x_2)$; i = 1; 2; denotes ...rm i's inverse demand function. The ...rst order conditions are given by:

$$p_1 + x_1 \frac{@p_1}{@x_1} = 0;$$

 $p_2 + x_2 \frac{@p_2}{@x_2}; r = 0:$

Changing the strategic variable from quantity to price adds an important new exect to the market competition stage: when choosing price, ...rm 1 considers not only its exect on own market pro...ts but also on ...rm 2's demand, that determines its royalty revenues. In this case they solve respectively:

$$\begin{split} &\mathsf{Max}_{p_1}\mathsf{fp}_1x_1(p_1;p_2)\,+\,\mathsf{rx}_2(p_1;p_2)\mathsf{g};\\ &\mathsf{Max}_{p_2}\mathsf{fp}_2x_2(p_1;p_2)\,\,\mathbf{j}\,\,\,\mathsf{rx}_2(p_1;p_2)\mathsf{g}; \end{split}$$

where $x_i(p_1; p_2); i = 1; 2$ denotes the direct demand functions. The ...rst order conditions are in this case:

$$x_1 + p_1 \frac{@x_1}{@p_1} + r \frac{@x_2}{@p_1} = 0;$$

 $x_2 + p_2 \frac{@x_2}{@p_2}; r \frac{@x_2}{@p_2} = 0;$

Comparing the …rst order conditions under Cournot and under Bertrand competition, we can see that in the latter case, a new term appears in the …rst equation (the third term) that provides …rm 1 with an additional incentive to behave less aggressively in the market stage: by strategically setting a higher price it increases …rm 2's demand and thus, its royalty revenues. Observe that the new e¤ect is absent when …rms choose quantities because, in that case, …rm 2's demand is not a¤ected by the decision (on output) taken by …rm 1. That is, the royalty not only determines …rm 2's marginal cost but it also works as a collusive device. This explains that, contrary to the Cournot case, even if the patentee sets r = c and f = 0; …rm 2 would strictly prefer signing that contract to the statu quo in order not to lose the collusive e¤ect mentioned above. In fact, by using a continuity argument one may argue that …rm 2 would be willing to accept contracts such that r > c. However, we will not consider that possibility because it would not a¤ect any of the qualitative results and one could argue that …rm 2 would not produce using the new technology and, therefore, no royalties would be paid.

The expressions for the equilibrium outputs, prices, pro...ts and total incomes for both types of competition can be found in the appendix.

We start the analysis by scenario 1, comparing two-part tari¤ licensing with a merger.

3.1. Merging vs. two-part tari¤ licensing

Observe that, if allowed by the antitrust agency, the ...rms will always choose to merge. On the other hand, as two-part tari¤ licensing is always pro...table for the patentee, if a merger is not allowed, licensing will take place. Intuitively, consider the simple contract r = c, f = 0. Under Cournot competition, the patentee would obtain the same market pro...ts as in the statu quo but the royalty revenues would make him strictly better o¤. Under Bertrand competition, the collusive e¤ect produced by the royalty would make licensing be even more

pro...table. Therefore, in order to design the optimal merger policy we have just to compare social welfare under a merger and two-part tari¤ licensing.

In order to do that, we have ...rst to obtain the optimal two-part tari¤ licensing contract, that is, the contract that maximizes the patentee's total pro...ts. That contract solves:

where $x_i(r)$ and $\frac{1}{4}i(r)$ denote ...rm i's equilibrium output and pro...ts under a licensing contract including a royalty r, and $\frac{1}{2}c$ denotes ...rm 2's pro...ts in the statu quo when its marginal cost is c.⁶Observe that the second constraint implies that f cannot be negative.

That program can be rewritten in a simpli...ed way. As the ...rst constraint is always binding, it can be substituted in the objective function. The maximization problem thus becomes:

Solving this program directly results in the optimal contract. For the case of Cournot it is given by:

$$\begin{aligned} r^{\mu} &= \text{minfc}; r_{c}^{\emptyset}g; \text{ where } r_{c}^{\emptyset} &= \frac{\circ(2_{1}^{\circ}\circ)^{2}}{2(4_{1}^{\circ}3^{\circ}2)}; \\ f^{\mu} &= \frac{4}{2}(r^{\mu}) \; j \; \frac{4}{2}(c); \end{aligned}$$

and for Bertrand competition by:

$$r^{\pi} = \text{minfc}; r_{B}^{0}g; \text{where } r_{B}^{0} = \frac{\circ (2+\circ)^{2}}{2(4+5^{\circ}^{2})};$$

 $f^{\pi} = \frac{1}{2}(r^{\pi}) |_{2} |_{2}(c):$

It is important to notice that the optimal two-part tarix licensing contract includes a positive royalty, that distorts the licensee's marginal costs. The patentee uses the royalty to soften ex-post market competition and the fee to extract the increase in industry pro...ts generated by the use of the superior technology.

⁶Observe that under Cournot competition $\frac{1}{2}(c) = \frac{1}{2}(c)$, while this is not true under Bertrand competition, due to the collusive exect.

Next proposition derives the optimal merger policy for this scenario. Both a merger and the optimal two part tari¤ contract are anticompetitive. Hence, the sign of the comparison will depend on whether social welfare is a¤ected more negatively by the lower competition induced by a merger or by the distortion of the licensee's marginal cost induced by the licensing contract. The following proposition o¤ers a clear-cut result: regardless of the type of competition, two-part tari¤ licensing is always welfare superior to a merger.

Proposition 3.1. When two-part tarix licensing contracts are feasible, mergers should never be allowed.

Observe that the optimal merger policy derived in the proposition ...ts the prescription of the U.S. merger guidelines: when e¢ciency gains are not merger speci...c and can also be also achieved through licensing, mergers should be forbidden. That result arises in a context in which both ...xed fees and royalties are feasible. We will next proceed to derive the optimal competition policy for scenarios 2 and 3 respectively, where only one instrument, either a royalty or a ...xed fee, is feasible.

3.2. Merging vs. royalty licensing

The main di¤erence between this scenario and the previous one is that, now, a royalty is the only feasible instrument to license ...rm 1's patented technology and it has to be used not only to soften ex-post competition but also to appropriate the surplus generated by the superior technology. As a result, a greater royalty will be chosen by the patentee, leading to a greater distortion of the licensee's marginal cost, which opens the possibility that a merger becomes welfare superior to licensing.

The optimal royalty contract solves:

$$max_{r}f_{1}(r) + rx_{2}(r)g$$

s:t: $r \cdot c$:

Direct resolution of that program results in:

$$\begin{split} r^{*} &= \text{minfc}; r_{c}^{\texttt{M}}g; \text{where } r_{c}^{\texttt{M}} = \frac{(2_{i} \ ^{\circ})(4+2^{\circ}i \ ^{\circ}2)}{2(8_{i} \ 3^{\circ}2)} \text{ , and} \\ r^{*} &= \text{minfc}; r_{B}^{\texttt{M}}g; \text{ where } r_{B}^{\texttt{M}} = \frac{8+^{\circ}3}{16+2^{\circ}2}; \end{split}$$

for Cournot and Bertrand competition respectively. It can be easily veri...ed that the optimal royalties are positive and greater than the corresponding ones in scenario 1, where both royalties and fees were feasible.

Next, we shall proceed to compare a merger and royalty licensing from a social point of view in order to derive the optimal merger policy for this scenario.

Proposition 3.2. When only royalties are feasible, for large enough innovations ($c > c^{ml}$ for Cournot and $c > c^{ml^0}$ for Bertrand), mergers should be allowed by the antitrust authority.

When only royalties are feasible for the patentee, the optimal royalty is greater than in the case where both royalties and fees can be used, which negatively a¤ects social welfare. This is why, for large enough innovations and regardless of the type of competition, a merger becomes welfare superior to licensing and, therefore, it should be allowed by the antitrust authorities. On the other hand, for small innovations the royalty imposed by the patentee is constrained to be small and, hence, licensing remains welfare superior to a merger. In that case, mergers should be forbidden. Note that the result holds regardless of the degree of product di¤erentiation. However, it can be seen that as the goods become closer substitutes, the threshold values c^{ml} and c^{ml⁰} increase. The reason is that closer substitutive goods imply more intense competition, which makes a merger relatively more anticompetitive than a licensing contract, thus decreasing the region where mergers should be allowed.

Next, we shall proceed to derive the optimal merger policy in scenario 3, where a ...xed fee is the only feasible instrument to license the superior technology.

3.3. Merging vs. ...xed fee licensing

Licensing by means of a ...xed fee allows the transfer of the superior technology without reducing competition. Therefore, ...xed fee licensing is welfare superior to a merger. However, for large enough innovations and close enough substitute goods, licensing by means of a fee becomes unpro...table for the patentee (as shown by Katz and Shapiro (1985) for the case of homogeneous goods, the e¢ciency gains can be more than compensated by the rent dissipation e¤ect, which drives down duopoly pro...ts). In that case, a merger becomes the

only exective instrument to transfer the superior technology and, therefore, it should be allowed whenever it increases social welfare relative to the statu quo, which tends to occur precisely for large innovations. We will present the results for each type of competition in a separate subsection. While the analysis of licensing pro...tability follows a similar pattern in both cases, the analysis of the merger policy is much more complex for Bertrand competition and it requires a detailed attention. Let us start by the case of Cournot competition.

3.3.1. Cournot competition

Next proposition characterizes the conditions under which ...xed fee licensing is not pro...table for the patentee.

Proposition 3.3. Under Cournot competition, if $^{\circ} > 0.82$ and $c > c^{L}$, licensing by means of a ...xed fee becomes unpro...table for the patentee.

The key point to explain the result is that, given that the patentee always binds the licensee's participation constraint through the ...xed fee, ...xed fee licensing is pro...table only if industry pro...ts increase as a consequence of the licensing contract. When the goods are very di¤erentiated, competition is not intense and industry pro...ts increase regardless of the size of the innovation. For the case of close substitutes however, the trade-o¤ between the e¢ciency e¤ect and the rent dissipation e¤ect becomes relevant. For small innovations, the latter e¤ect is small and it is dominated by the former, given that the improved e¢ciency is applied over many units of output that would be produced by ...rm 2 under the statu quo. For large innovations however, ...rst, the rent dissipation e¤ect of transferring the innovation is much higher and, second, the improved e¢ciency is applied to fewer units of output that would be produced by ...rm 2 would be produced by ...rm 2 would be produced by ...rm 2 would decrease, making ...xed fee licensing unpro...table for the patentee.

Next proposition establishes the conditions under which a merger is welfare superior to the statu quo.

Proposition 3.4. Under Cournot competition, a threshold value c^{ms} always exists such that a merger is welfare improving if and only if $c c^{ms}$.

The above proposition can be seen as the optimal merger policy when the e¢ciency gains attained through a merger are merger speci...c. Taking into account that c^{ms} increases with °, it provides a nice illustration of the trade-o¤ between competition and e¢ciency involved in a merger. While the size of the anticompetitive e¤ect is inversely related to the degree of product di¤erentiation °, the e¢ciency e¤ect is captured by c; the size of the innovation. Therefore, the greater the anticompetitive e¤ect (the greater °) the greater the size of the e¢ciency gain (the greater c) required for the merger to be welfare superior to the statu quo.

Next proposition combines Propositions 3.3 and 3.4 in order to derive the optimal merger policy.

Proposition 3.5. Under Cournot competition, when only a ...xed fee can be included in the licensing contract, if $\circ \cdot 0.82$, a merger should never be allowed; if $\circ > 0.82$, it should be allowed if and only if c $_{\circ}$ c^L:

The result is driven by the fact that $c^{L} > c^{ms}$. In other words, in the region where ...xed fee licensing is not pro...table for the patentee, a merger is welfare improving and it should then be allowed. A direct implication of the proposition is that under the optimal merger policy, technology is always transferred.

Let us derive next the optimal merger policy for scenario 3 under Bertrand competition.

3.3.2. Bertrand competition

Next proposition characterizes the conditions under which ...xed fee licensing is not pro...table for the patentee.

Proposition 3.6. Under Bertrand competition, if $^{\circ} > 0.61$ and $c > c^{L^0}$, licensing by means of a ...xed fee becomes unpro...table for the patentee.

The intuition for the result is exactly the same as for the case of Cournot competition. The only di¤erence is that, given that Bertrand is a more intense type of competition, we reach the region where licensing is not pro…table for the patentee even for lower values of ° than for the Cournot case. Next proposition derives the conditions under which a merger is welfare superior to the statu quo.

Proposition 3.7. Under Bertrand competition, three threshold values c^{ms^0} , c^n and $c^{ms^{00}}$; with $c^{ms^0} \cdot c^n < c^{ms^{00}}$ exist such that when ° · 0:69, a merger is welfare superior to the statu quo if and only if c $c^n c^{ms^0}$; when 0:69 < ° · 0:71, if either $c^{ms^0} \cdot c \cdot c^n$, or c c^n , or c $c^{ms^{00}}$, and when ° > 0:71 if and only if c $c^n c^{ms^{00}}$, where the values of c^{ms} ; c^{ms^0} , c^n and $c^{ms^{00}}$ are provided in the appendix.

Observe that except for the intermediate interval $0:69 < \circ \cdot 0:71$; the intuition behind the result is similar to the one obtained for Cournot competition. Namely, mergers should be allowed for large enough innovations such that their e¢ciency e¤ect outweights their anticompetitive e¤ect. In those cases, the design of the optimal merger policy simply consists of ...nding the corresponding unique cut-o¤ value. Notice that this cut-o¤ value is higher for the case of Bertrand than for Cournot because competition is more intense in the former (see Vives (1985)).

The previous simple intuition, however, does not work for the intermediate interval in the above proposition. The striking point in that interval is that, as the size of the innovation increases, the optimal merger policy decision switches from approving the merger to forbidding it. This implies that more than one cut-o^x value is required to completely de...ne the optimal merger policy.

Figure 1 plots, for ° = 0:70, welfare under both a merger (Wm) and the statu quo (Wsq) as a function of c: While welfare under a merger is constant in c; welfare under the statu quo follows a more complex pattern: as c increases from zero, good 2 is produced more ineCciently but production is being concentrated on the more eCcient ...rm. For high values of c the latter exect dominates, which explains the increasing part of the function. When c reaches the region where ...rm 2 does not produce but ...rm 1 cannot charge the monopoly price, ($c^P \cdot c < c^M$), additional increases of c have the only exect of increasing prices, and no eCciency exect is involved, which explains that the function decreases. Finally, for drastic innovations ($c c C^M$), the welfare function is constant in c.

The reason why we obtain a unique cut-o^x value except for the interval 0:69 < ° · 0:71 is not that the shape of the statu quo welfare function changes with parameter °; but only that it shifts up as ° increases. When ° is low, two points are to be considered: ...rst, that a merger is always superior to the statu quo in the regions where ...rm 2 in not active (that is, the peak in Figure 1 is below the merger welfare function) and, second, that in c = 0, the statu quo is welfare superior to a merger. Both points jointly imply that only one cut-o^x value does exist. On the other hand, when ° is high, ...rst, mergers are never socially desirable in the region where both ...rms are active and, second, in c = c^M a merger is superior to the statu quo. Again, both points jointly imply that only one cut-o^x value exists (see Figure 1).

Next proposition combines Propositions 3.6 and 3.7 to derive the optimal merger policy for the Bertrand case.

Proposition 3.8. Under Bertrand competition, if $^{\circ} \cdot 0.61$, mergers should never be allowed; if $0.61 \cdot ^{\circ} \cdot 0.69$, mergers should be allowed if and only if $c c^{L^0}$; if $0.69 < ^{\circ} \cdot 0.71$, if either $c^{L^0} \cdot c \cdot c^n$ or $c c^{ms^{(0)}}$; ...nally, if $^{\circ} > 0.71$, if and only if $c c^{ms^{(0)}}$.

The above proposition shows ...rst, that in the region where both ...rms are active (c < c^P), mergers should be allowed only for intermediate values of the di¤erentiation parameter (low values of ° makes ...xed fee licensing always pro...table and high values prevent mergers from being socially desirable) and either for large enough innovations (for 0:61 · ° · 0:69, small innovations prevent mergers from being socially desirable) or for intermediate innovations (for 0:69 < ° · 0:71 small and large innovations prevent mergers from being socially desirable). Second, in the region where in absence of licensing ...rm 2 would not be active (c $_{\circ}$ c^P), a new case appears where above a certain threshold value of c, mergers should again be allowed (notice that in this region, welfare under the statu quo is always decreasing in c because, now, ...rm 2 is not active and additional increases of c do not transfer any ine¢cient output to the more e¢cient ...rm).

Observe that under Bertrand competition, contrary to what happens under Cournot, the optimal merger policy does not necessarily lead to technology transfer. For example, in ...gure1, for innovations lying in the interval ($c^n, c^{ms^{00}}$), licensing by a ...xed fee is not pro...table

for the patentee and, at the same time, a merger is not welfare improving, which implies that it should be forbidden. In that interval, the superior technology is not transferred under the optimal merger policy.

Summarizing, from the optimal merger policy derived in Propositions 3.1, 3.2, 3.5 and 3.8, an interesting policy implication can be derived. When licensing is an alternative to a merger for transferring technology, a more restrictive optimal merger policy is called for. This argument seems to be present in the 1997 HMG, that prescribes to forbid mergers whenever the e¢ciency gains can be alternatively achieved through licensing. The optimal merger policy derived in the paper exactly ...ts that prescription only when both ...xed fees and royalties are feasible instruments to license the superior technology. Otherwise, the possibility of licensing cannot be used as a de...nitive argument against mergers. In particular, it may be too restrictive because it may lead to forbid welfare improving mergers: in scenario 2, it may occur because the patentee imposes greater royalties that additionally distort the licensee's output, reducing welfare. On the other hand, in scenario 3 because, as Propositions 3.3 and 3.6 show, ...xed fee licensing is not always pro...table for the patentee and, in those cases, a merger is the only e¤ective instrument to transfer the superior technology.

4. WELFARE REDUCING LICENSING

So far, we have focused on deriving the optimal merger policy when licensing is an alternative to a merger to transfer technology. In this section we want to go a bit further by taking into account a result that is ...rst introduced in the licensing literature in Faulí-Oller and Sandonís (2000a), namely, the possibility that, under Bertrand competition, a licensing contract reduces social welfare⁷. This possibility seems to suggest the convenience of designing not just the optimal merger policy, but a more general competition policy that may forbid not only mergers but also licensing contracts whenever they reduce welfare. For example, in scenario 2, we compared a merger and royalty licensing. The optimal merger policy prescribed just to allow the merger whenever it is welfare superior to licensing. However, using that rule, we could be approving welfare reducing mergers. On the other hand, whenever welfare under licensing is higher than under a merger, we should not only forbid mergers but also check whether or not the licensing contract improves social welfare. If that is not the case, we should forbid not only mergers but also licensing but also licensing.

From a formal point of view, in the ...rst stage of the game, the antitrust authority should decide now whether or not to allow for a merger and also for a licensing contract. Observe that it makes sense to check whether a licensing contract improves social welfare only when (i) the contract includes a royalty (licensing the innovation by means of a ...xed fee is necessarily welfare improving: it allows the transfer of the technology without reducing competition at all) and (ii) competition is à la Bertrand (it is only under Bertrand competition when the collusive exect of the royalty arises). Therefore, in this section we have to derive the optimal competition policy only for the case of Bertrand competition and scenarios 1 and 2, where the licensing contract includes a royalty. For the rest of the cases, the optimal competition policy would be just the optimal merger policy derived in the last section.

Next proposition establishes the conditions under which two-part tarix licensing reduce social welfare and derives the optimal competition policy for scenario 1 under Bertrand competition.

⁷The result that a licensing contract can reduce social welfare has also been obtained by Erutku and Richelle (2000) in a context of non-linear contracts and Cournot competition.

Proposition 4.1. Under Bertrand competition, for close enough substitute goods ($^{\circ}$ > 0:72), two threshold values of the size of the innovation (c) always exist such that for innovations lying within that interval, licensing reduces social welfare. Thus, within that interval we should forbid not only mergers but also licensing.

The intuition for the result is the following: ...rst, as the goods become closer substitutes licensing becomes more anticompetitive because the optimal royalty increases. Second, for low values of c, the royalty is constrained to be small and therefore, licensing does not a¤ect competition a lot. As the innovation becomes larger, however, the patentee charges a greater royalty that makes licensing more anticompetitive. Both points together explain that for low values of c and ° licensing is welfare improving. Third, for drastic innovations, in the absence of licensing we would have a monopoly in market 1 while, under licensing, we would have a duopoly (see Proposition 3.2). For drastic innovations then (and by continuity, for near drastic innovations as well), licensing must be welfare superior to the statu quo. The three points together explain the result in the above proposition. As a conclusion, the antitrust agency should take into account not only the anticompetitive e¤ect of a merger but also the possibility that a licensing contract reduces social welfare. In those cases, the optimal policy prescription should be to forbid not only mergers (given that two-part tari¤ licensing is always welfare superior to a merger) but also licensing.⁸

The same analysis may be done for scenario 2, where only a royalty can be included in the licensing contract. As before, under Bertrand competition, for close enough substitutes, we ...nd an interval where royalty licensing reduces social welfare. Next proposition formalizes the result.

Proposition 4.2. Under Bertrand competition, for close enough substitute goods (° > ⁸Of course, we would like to o¤er a more simple rule regarding when to forbid welfare reducing licensing

contracts. For example, we could just forbid the use of royalties in licensing contracts. With that rule, the antitrust agency would completely eliminate the possibility that a licensing contract hurts social welfare because, as we know, ...xed fee licensing is always welfare improving. That policy would be optimal, however, only in a second-best sense because, as we already know (see scenario 3), for close enough substitute goods and large enough innovations, ...xed fee licensing becomes unpro...table for the patentee. It can be easily seen that, if royalties are forbidden, some welfare improving licensing agreements would not take place.

0:60), two threshold values for the size of the innovation (c) always exist such that for innovations lying within that interval, licensing by means of a royalty reduces social welfare.

Observe that licensing by means of a royalty reduces social welfare even for more di¤erentiated goods (° _ 0:60) than two-part tari¤ licensing does (° _ 0:72). The reason is that, in the former case, the optimal royalty is greater, leading the licensing contract to be even more anticompetitive.

Next proposition compares social welfare under a merger, royalty licensing and the statu quo in order to derive the optimal competition policy for scenario 2.

Proposition 4.3. Under Bertrand competition:

(i) if $^{\circ}$ < 0:69, a threshold value $c^{ml^{0}}$ always exist such that mergers should be allowed if and only if c $_{\circ}$ $c^{ml^{0}}$. In this interval, a licensing contract is always welfare improving.

(ii) if ° _ 0:69, two threshold values of c always exist such that for small enough innovations (those lying to the left of the interval formed by those values) licensing is welfare superior to both a merger and the statu quo and thus, only mergers should be forbidden; for innovations lying within that interval, either a merger is welfare superior to both licensing and the statu quo and then no restriction should be imposed, or the statu quo is welfare superior to licensing and also to a merger and then both mergers and royalty licensing should be forbidden; ...nally, for large enough innovations (to the right of that interval), a merger domains and then no restriction should be imposed by the antitrust agency.

For dimerentiated enough goods (° < 0:69), competition is not intense and in the region where licensing is welfare superior to a merger it is also welfare superior to the statu quo and, similarly, in the region where a merger is welfare superior to licensing it is also welfare superior to the statu quo, and it should then be allowed. For close enough substitutes (° _ 0:69), however, dimerent possibilities arise. On the one hand, in the region where licensing is welfare superior to a merger, for large enough innovations, the statu quo may become welfare superior to licensing, and hence, in that region not only mergers but also licensing should be forbidden. On the other hand, in the region where a merger is welfare superior to licensing, for intermediate sizes of the innovation, the statu quo becomes welfare superior to a merger, and thus both mergers and licensing should be forbidden.(see ...gure 2)

Figure 2 plots, for $^{\circ} = 0.70$, welfare under a merger (Wm), the statu quo (Wsq) and the optimal licensing contract (WI) as a function of c. As we can see in the ...gure, for small innovations (c < c^{m1⁰}), royalty licensing is welfare superior to both, a merger and the statu quo, for innovations within the interval (c^{m1⁰}; cⁿ), a merger is the socially preferred regime, for innovations within the interval (cⁿ; c^{ms⁰⁰}) the statu quo becomes the socially preferred option and, ...nally, for large innovations (c > c^{ms⁰⁰}), a merger becomes again welfare superior to the other two regimes.

5. CONCLUSIONS

The traditional merger policy analysis prescribes to allow a merger if and only if it generates e¢ciency gains that compensate for their negative impact on competition. In this paper, we extend this analysis by considering also the existence of an alternative mechanism that may allow ...rms to attain those e¢ciencies, namely, patent licensing. In that case, a more restrictive merger policy is called for. The 1992 U.S. Horizontal Merger Guidelines was revised in 1997 to incorporate this idea, and it prescribes to forbid mergers whenever e¢ciency gains are not merger speci...c, but can also be achieved through licensing. In this work, we have shown that the prescription of the 1997 HMG is too restrictive. In particular, for large innovations mergers tend to be superior to licensing: when royalties are not feasible, it is true because large innovations make licensing unpro...table and, at the same time, make mergers socially desirable; on the other hand, when ...xed fees are not feasible, because for large innovations the patentee tends to impose high royalties that distort total output and welfare.

Without considering the possibility of licensing, the traditional merger policy is more restrictive the closer substitutes the goods are, because a merger becomes more anticompetitive. This is still true in our framework whenever royalties are feasible. When only fees are feasible, however, the result is reversed: mergers should be allowed only when the goods are good substitutes. The reason for this counterintuitive result is that what determines the merger policy in that case is whether licensing is pro...table or not, and it turns out that it is not pro...table when the goods are close substitutes.

Our analysis is useful to design not only the optimal merger policy but a more general competition policy, in the sense that it also allows us to prescribe whether licensing should be allowed or not. As we have shown, while under Cournot competition licensing is always welfare improving, under Bertrand competition the royalty works as a collusive device that allows the patentee to increase prices, producing a negative exect on social welfare. As a consequence, for large enough, non-drastic innovations, licensing may reduce social welfare and, thus, it should be forbidden by the antitrust authorities.

Another interesting question arising from our results is whether the design of the optimal

competition policy always favors technology transfer. The answer is negative. On the one hand, under Bertrand competition, cases exist where not only mergers but also licensing agreements are forbidden under the optimal competition policy, preventing the ...rms from transferring the superior technology. On the other hand, a special case exist where mergers are forbidden even though they are the only exective instrument to transfer the superior technology: when we consider ...xed fee contracts, for large enough innovations and close enough substitutes, licensing becomes unpro...table for the patentee and, given that competition is intense, a merger is not welfare improving and it should then be forbidden. In those cases, the optimal competition policy also prevents the difusion of the patented innovation.

In this paper, we have assumed that a patented process innovation already exist and analyze the incentives of the patentee to transfer the innovation through a licensing contract and also through a merger, and then compare their exect on social welfare in order to design the optimal competition policy. An interesting extension of the paper would be to go one step backwards and consider also a previous stage in which the ...rms decide their R&D investments, and then analyze how the incentives of the ...rms to undertake R&D are axected by dixerent antitrust policies. In that case, in order to design the optimal competition policy we should compare the anticompetitive exect of a merger with the both the eventual e¢ciency gains and the increase in the incentives of the ...rms to undertake R&D. As a result and compared with our setting, we could prescribe in that case a less severe merger policy.

6. APPENDIX

The third stage Nash equilibrium

For the case of Cournot competition, the third stage ...rms' Nash equilibrium outputs, prices, pro...ts and total incomes when ...rm 2 has accepted a (f;r) contract with $r \cdot c$, are given by:

$$\begin{aligned} x_1(r) &= \min f \frac{2 i \circ (1 i r)}{4 i \circ 2}; \ \frac{1}{2}g; \ x_2(r) &= \max f \frac{2(1 i r) i \circ}{4 i \circ 2}; \ 0g; \\ & & & \\$$

By substituting c for r in the above expressions, the equilibrium outputs and pro...ts under the statu quo situation are obtained. Notice that when ...rm 2 is not active, ...rm one produces the monopoly output $x_1 = 1=2$:

Finally, we de...ne industry outputs and pro...ts under a merger. They are given by:

$$x_1^m = x_2^m = \frac{1}{2(1 + \circ)}; H^m = \frac{1}{2(1 + \circ)};$$

For the case of Bertrand competition, let us ...rst analyze the case of non-drastic innovations (c < c^M). The third stage Nash equilibrium prices, outputs and pro...ts, when ...rm 2 has accepted a (f; r) contract with $r \cdot c$, are given by⁹:

$$p_{1}(r) = \frac{(2 i \circ i \circ 2) + 3 \circ r}{4 i \circ 2}; \quad p_{2}(r) = \frac{(2 i \circ i \circ 2) + (2 + \circ 2)r}{4 i \circ 2};$$
$$x_{1}(r) = \frac{(2 + \circ) i \circ r(1 + \circ)}{(1 + \circ)(4 i \circ 2)}; \quad x_{2}(r) = \frac{(2 + \circ) i \circ 2r(1 + \circ)}{(1 + \circ)(4 i \circ 2)};$$
$$y_{1}(r) = p_{1}(r) x_{1}(r); \quad y_{2}(r) = (p_{2}(r) i r) x_{2}(r):$$

On the other hand, if r > c, the new technology would not be used and the statu quo would prevail, which for $c < c^{P}$, where $c^{P} = \frac{(2_{i} \circ_{i} \circ^{2})}{2_{i} \circ^{2}}$, leads to the following equilibrium prices, outputs and pro...ts:

⁹In order to check that the interior equilibrium is exectively an equilibrium we have to check that no ...rm has an incentive to deviate by lowering its price in order to expel the competitor from the market. This would be the case only if $r > r^{M} = \frac{8+8^{\circ}+^{\circ 3}+^{\circ 4}+2}{2(8+8^{\circ}+^{\circ 2}+^{\circ 3})}$. As $r^{M} > c^{M}$; the expressions below exectively represents the equilibrium for the non-drastic case.

$$P_{1}(c) = \frac{(2 i \circ i \circ 2) + \circ C_{2}}{4 i \circ 2}; P_{2}(c) = \frac{(2 i \circ i \circ 2) + 2C_{2}}{4 i \circ 2};$$

$$X_{1}(c) = \frac{(2 i \circ i \circ 2) + \circ C_{2}}{4 i 5 \circ 2 + \circ 4}; X_{2}(c) = \frac{(2 i \circ i \circ 2) i C_{2}(2 i \circ 2)}{4 i 5 \circ 2 + \circ 4};$$

$$\downarrow_{1}(c) = P_{1}(c) X_{1}(c); \downarrow_{2}(c) = (P_{2}(c) i c) X_{2}(c):$$

In that region, both ...rms are active.

If, on the other hand, $c^{P} \cdot c < c^{M}$, they are given by:

$$P_{1}(c) = \frac{(i \ 1 + \circ) + c}{\circ}; P_{2}(c) = c;$$
$$X_{1}(c) = \frac{1 \ i \ c}{\circ}; X_{2}(c) = 0;$$

In that region, ...rm 2 is not active but ...rm 1 cannot charge the monopoly price.

Let us next analyze the third stage equilibrium for the case of drastic innovations (c c^M) when ...rm 2 has accepted a (f;r) contract with r \cdot c. If c^M \cdot r < r^M, where the value of r^M is given in the previous footnote, both an interior and a monopoly equilibrium exist; the interior one is given by the above expressions and at the monopoly equilibrium, $x_1 = p_1 = 1=2$ and $\frac{1}{4} = 1=4$. On the other hand, if r $_{_{\rm o}}$ r^M, the monopoly equilibrium arises.¹⁰ Finally, for r > c, the statu quo would prevail, with ...rm 1 becoming a monopolist and again $x_1 = p_1 = 1=2$ and $\frac{1}{4} = 1=4$.

Solving this program directly results in the optimal two-part tarix contracts shown in the paper for both Cournot and Bertrand competition.

Proof of proposition 3.1

Let us denote by W^m and W^r social welfare under a merger and under a licensing contract with a royalrty r Under Cournot, we have that $W^m > W^r$ if and only if $c > c^{ml}$, where $c^{ml} = \frac{8_i \ 6^{\circ 2} + 2^{\circ 3}_i}{2(i \ 4_i \ 4^{\circ} + 3^{\circ 2} + 3^{\circ 3})}$. As c^{ml} , r_c^0 ; licensing is always socially preferred to a merger.

Under Bertrand, $W^m > W^r$ if and only if $c > c^{ml^0}$; where $c^{ml^0} = \frac{(2+\circ)(i \ 4+4^{\circ 2}+2^{\circ 3}i \ 2^\circ+(2i \ \circ))}{2(4+4^\circ+5^{\circ 2}+5^{\circ 3})}$: As c^{ml^0} , r_B^0 ; licensing is always socially preferred to a merger. ■

¹⁰In fact, the case $r > c^{M}$, is not relevant for the analysis, as the optimal royalty is never greater than c^{M} .

Proof of Proposition 3.2

With Cournot, $c^{ml} \cdot r_c^{0}$ and therefore for $c > c^{ml}$ a merger is socially preferred to licensing.

With Bertrand, $c^{ml^0} \cdot r^{0}_B$ and therefore for $c > c^{ml^0}$ a merger is socially preferred to licensing.

Proof of Proposition 3.3

For Cournot competition, directly comparing industry pro...ts under ...xed fee licensing with the statu quo situation, we obtain that $\aleph_1(0) + \aleph_2(0) < \aleph_1(c) + \aleph_2(c)$ if and only if $^{\circ} > 0.82$ and $c > c^{\perp}$, where $c^{\perp} = \frac{2(4 + 2^{\circ})^2}{4 + 2^{\circ}}$:

Proof of Proposition 3.4

For Cournot competition, comparing welfare under both a merger and the statu quo directly produces the result, where $c^{ms} = \frac{i \ 24_i \ 8^\circ + 18^{\circ 2}_i \ 2^{\circ 4} + (4_i \ \circ)}{2(i \ 12_i \ 12^\circ + \circ^2 + \circ^3)}$.

Proof of Proposition 3.5

Whenever licensing is not privately pro...table and mergers are socially preferred to the statu quo, mergers should be allowed. This proposition just brings together the corresponding conditions from propositions 3.3 and 3.4, taking into account that $c^L \ c^{ms}$.

Proof of Proposition 3.6

We have to compare industry pro...ts under ...xed fee licensing with the statu quo situation in the two relevant cases.

If $c \cdot c^{P}$, $\mathcal{V}_{1}(0) + \mathcal{V}_{2}(0) < \frac{1}{1}(c) + \frac{1}{2}(c)$ if $\circ > 0.65$ and $c > c^{L^{0}}$.

If $c > c^{P}$, $\frac{1}{4_{1}(0)} + \frac{1}{4_{2}(0)} < \frac{1}{1}(c) + \frac{1}{2}(c)$ if $^{\circ} > 0.65$ and if $0.61 \cdot ^{\circ} \cdot ^{\circ} 0.65$, if $c > c^{L^{00}}$, where $c^{L^{00}} = \frac{4_{i} 3^{\circ 2} + ^{\circ 3} i \circ ^{\circ} \frac{1}{4 + 4^{\circ} + 5^{\circ 2} i 2^{\circ 3} + ^{\circ 4}}{4 + 2^{\circ} i 2^{\circ 2}}$ and $c^{L^{0}} = \frac{2(i 2 + ^{\circ} + ^{\circ} 2)^{2}}{4_{i} 3^{\circ 2} i \circ ^{\circ 4}}$. The statement in the proposition directly follows the previous inequalities.

Proof of Proposition 3.7

We shall proceed to compare welfare under a merger and under the statu quo in the two relevant regions.

 $\frac{|\operatorname{fc}_{2i} c^{P}, W^{m}}{\frac{2i}{2(1+^{\circ}+2^{\circ})^{2}}} \stackrel{\text{o}}{\xrightarrow{}} W^{sq} \text{ if } \stackrel{\circ}{\xrightarrow{}} 0:69 \text{ and } c \stackrel{\text{o}}{\xrightarrow{}} c^{ms^{00}}, \text{ where } c^{ms^{00}} = and W^{sq} \text{ denotes welfare under the statu quo.}$ The statement in the proposition directly follows the previous inequalities.

Proof of Proposition 3.8

We have that for $\circ \cdot 0.61$ licensing is always pro...table for the patentee and mergers should not be allowed. For $0.61 \cdot \circ \cdot 0.65$, we have $c^{L^{00}} > c^{ms^0}$; which implies that mergers should be allowed in this region for c $c^{L^{00}}$: For $0.65 \cdot \circ \cdot 0.69$, we have $c^{L^0} > c^{ms^0}$, which implies that mergers should be allowed in this region for c c^{L^0} . For $0.69 < \circ < 0.710$, we have $c^{ms^0} < c^{L^0} < c^n$ and $c^{ms^{00}} > c^n$; which implies that mergers should be allowed in this region if either $c^{L^0} \cdot c \cdot c^n$ or $c c^{ms^{00}}$. For $0.710 < \circ < 0.7112$, we have that $c^n < c^{L^0} < c^{ms^{00}}$, which implies that mergers should be allowed in this region for c $c^{ms^{00}}$. For $0.710 < \circ < 0.7112$, we have that $c^n < c^{L^0} < c^{ms^{00}}$, which implies that mergers should be allowed in this region for c $c^{ms^{00}}$. Finally, for $\circ > 0.7112$, c^n and c^{ms^0} does not exist and $c^{L^0} < c^{ms^{00}}$, which implies that mergers should be allowed in this region for c $c^{ms^{00}}$.

Proof of Proposition 4.1

The result follows from comparing social welfare under licensing and under the statu quo. For $\circ \cdot 0.72$, the latter is never superior. For $0.72 < \circ < 0.94$, the statu quo is superior if and only if $c^{11} < c < c^{12}$: Finally, if $\circ \int_{\frac{1}{3} + 16^{\circ}i} \frac{0.94}{132 + 16^{\circ}i} \frac{10^{\circ} + 2^{\circ} + 2^{\circ}i}{132 + 16^{\circ}i} \frac{10^{\circ} + 2^{\circ}i}{1$

Proof of Proposition 4.2

The result follows from comparing welfare under licensing and under the statu quo. For $\circ \cdot 0.60$, the latter is never superior. If $0.60 < \circ < 0.94$, the statu quo is superior if and only if $c^{I1} < c < c^{I4}$. Finally, if $\circ \, 0.94$ if and only if $c^{I5} < c < c^{I4}$, where $c^{I1} = \frac{2(8_{1} \cdot 8^{\circ} \cdot 2^{\circ} 2 + 4^{\circ} 3_{1} \cdot 6^{\circ} - 5)}{16_{1} \cdot 8^{\circ} 2_{1} \cdot 3^{\circ} 4}$, $c^{I4} = \frac{128_{1} \cdot 96^{\circ} 2_{1} \cdot 30^{\circ} 4_{1} \cdot 2^{\circ} + (8^{\circ} + 3^{\circ})}{2(64 + 64^{\circ} + 16^{\circ} 2 + 4^{\circ} 3 + 41^{\circ} 4_{1} \cdot 2^{\circ} 5 + 5^{\circ} 6)}$, and $c^{I5} = \frac{128_{1} \cdot 96^{\circ} 2_{1} \cdot 30^{\circ} 4_{1} \cdot 2^{\circ} 6_{1} \cdot (8^{\circ} + 3^{\circ})}{2(64 + 64^{\circ} + 16^{\circ} 2 + 16^{\circ} 3 + 9^{\circ} 4 + 9^{\circ})}$. This proof joint with Proposition 3.1 implies that within that interval, we should forbid not only mergers but also licensing.

Proof of Proposition 4.3

By using the results derived in propositions 3.2, 3.7 and 4.2 and given that $c^{I1} < c^n$ and $c^{ms^0} < c^{I4}$ all we have to do is comparing c^{mI^0} , c^{I1} and c^{ms^0} . In particular, if ° < 0:60, licensing is always welfare superior to the statu quo (c^{I1} does not exist), the statu quo welfare function crosses only once the merger welfare function (c^n and $c^{ms^{00}}$ do not exist) and $c^{ms^0} < c^{mI^0}$; if 0:60 < ° < 0:69, $c^{ms^0} < c^{mI^0} < c^{I1}$ and c^n and $c^{ms^{00}}$ does not exist.

If 0:69 < ° < 0:7111, $c^{ms^0} < c^{ml^0} < c^{l1}$ and the statu quo welfare function crosses three times the merger welfare function (c^n and $c^{ms^{00}}$ come into play). This implies that for $c < c^{ml^0}$ licensing dominates; for $c^{ml^0} \cdot c < c^n$, a merger dominates; for $c^n \cdot c < c^{ms^{00}}$; statu quo dominates and for $c^{ms^{00}} \cdot c$; a merger again dominates.

If 0:7111 < ° < 0:7112; $c^{I1} < c^{mI^0} < c^{ms^0}$; which implies that for $c < c^{I1}$, licensing dominates; for $c^{I1} \cdot c < c^{ms^0}$ statu quo dominates; for $c^{ms^0} \cdot c < c^n$ a merger dominates; for $c^n \cdot c < c^{ms^{00}}$ statu quo dominates and for $c^{ms^{00}} \cdot c$ a merger again dominates.

If ° > 0:7112, c^{ms⁰} and cⁿ do not exist any longer. For 0:7112 < ° < 0:94, c^{I1} < c^{m1⁰} < c^{ms⁰⁰}, which implies that for c < c^{I1}, licensing dominates; for c^{I1} · c < c^{ms⁰⁰}; statu quo dominates and for c^{ms⁰⁰} · c a merger dominates. For ° > 0:94, c^{I5} < c^{m1⁰} < c^{ms⁰⁰}, which implies that for c < c^{I5}, licensing dominates; for c^{I5} · c < c^{ms⁰⁰}, statu quo dominates and for c^{ms⁰⁰} · c; a merger dominates.
